## Untwisted chiral CFT

- A Vertex Operator Algebra (VOA)  $\mathbb{V}$ , or a conformal net.
- $\operatorname{Rep}(\mathbb{V})$ , the category of  $\mathbb{V}$ -modules (satisfying...)
- Rep(V) is an abelian category. To make Rep(V) a tensor category, we need to study conformal blocks associated to V-modules. These are certain data associated to V-modules and pointed Riemann surfaces (assuming compactness throughout the talk).
- Genus-0 conformal blocks contain all the information of Rep(V). (Folklore: Higher genus data are determined by genus-0 ones.) But to prove deeper properties (e.g. rigidity, modularity, Verlinde formula, modular invariance, etc.), it is also necessary to study genus-1 conformal blocks.

## Twisted chiral CFT (i.e. orbifold theory)

- A (say) finite group G of automorphisms of a VOA  $\mathbb{U}$ .
- We want to study Rep(U<sup>G</sup>) where
  U<sup>G</sup> = {u ∈ U : gu = u ∀g ∈ G}. Since any U-module automatically restricts to a U<sup>G</sup>-module, Rep(U<sup>G</sup>) contains more information than Rep(U), and one cannot recover Rep(U<sup>G</sup>) from Rep(U).
- In good cases (e.g. U<sup>G</sup> is C<sub>2</sub>-cofinite), the study of Rep(U<sup>G</sup>) is more or less equivalent to the study of Rep<sup>G</sup>(U), which is the tensor category of G-twisted U-modules. (Kirillov, Müger, McRae, etc.)

## Permutation orbifold CFT

- For permutation orbifold CFTs, twisted modules and their conformal blocks can be reduced to the study of untwisted ones. We call this the permutation-twisted/untwisted correspondence.
- More precisely: Let E be a finite set (≈ {1,2,..., |E|}), let G be Aut(E) = {permutations of E} or its subgroup, acting by permutation on U = V<sup>⊗E</sup>.
- The correspondence says that G-twisted V<sup>⊗E</sup>-modules and their conformal blocks can be constructed from (untwisted)
  V-modules and conformal blocks. Moreover, the Riemann surface C on the untwisted side should be a (possibly) branched covering of the one C<sub>0</sub> on the twisted side.

イロト 不留下 不同下 不同下

#### What are twisted modules?

- Recall that  $\mathbb{V}$  is a vector space together with a vertex operation Y associating linearly to each u an operator-valued holomorhic function Y(u, z) over  $z \in \mathbb{C}^{\times} = \mathbb{C} \setminus \{0\}$ . Y(u, z) is a linear operator from  $\mathbb{V}$  to the "algebraic closure"  $\mathbb{V}^{cl}$ . But each  $Y(u)_n = \operatorname{Res}_{z=0} Y(u, z) z^n \frac{dz}{2i\pi}$  is a genuine linear operator on  $\mathbb{V}$ .
- A crucial property for Y is the Jacobi identity  $Y(u,z)Y(v,\zeta) \sim Y(v,\zeta)Y(u,z) \sim Y(Y(u,z-\zeta)v,\zeta).$
- For an untwisted  $\mathbb{V}$ -module  $\mathbb{W}$ , we also have a similar vertex operation  $Y_{\mathbb{W}}$ . This time, for each  $u \in \mathbb{V}$ ,  $Y_{\mathbb{W}}(u, z) : \mathbb{W} \to \mathbb{W}^{cl}$ , and for each  $u, v \in \mathbb{V}$ ,

 $Y_{\mathbb{W}}(u,z)Y_{\mathbb{W}}(v,\zeta) \sim Y_{\mathbb{W}}(v,\zeta)Y_{\mathbb{W}}(u,z) \sim Y_{\mathbb{W}}(Y(u,z-\zeta)v,\zeta).$

#### What are twisted modules?

Now, let G → U. If g ∈ G (with order |g|) and W is a g-twisted module, then Y(u, z) : W → W<sup>cl</sup> is single-valued over z<sup>1/|g|</sup> ∈ C<sup>×</sup>, and hence Y(u, z) depends on arg z. And Y<sub>W</sub>(gu, z) = Y<sub>W</sub>(u, e<sup>-2iπ</sup>z)

Here  $\arg(e^{-2\mathbf{i}\pi}z) = -2\pi + \arg z$ .

イロト 不得下 イヨト イヨト 二日

#### Construction of permutation-twisted modules

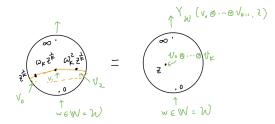

- Due to Barron-Dong-Mason ('02)
- First, assume  $g \in G$  has only one orbit, i.e.  $E = \{0, 1, \dots, k-1\}, g = (012 \cdots k - 1).$  Let  $\omega_k = e^{-2i\pi/k}$ . Then for each  $\mathbb{V}$ -module  $\mathbb{W}$ , we can construct a g-twisted  $\mathbb{V}^{\otimes E}$ -module  $\mathcal{W}$  which equals  $\mathbb{W}$  as vector spaces, and

$$Y_{\mathcal{W}}(v_0 \otimes v_1 \otimes \cdots \otimes v_{k-1}, z) = \prod_{j=0}^{k-1} Y_{\mathbb{W}}(\star v_j, (\omega_k)^j z^{1/k})$$

Here  $\star$  are linear operators which account for the change of coordinate. And  $\arg((\omega_k)^j z^{1/k}) = -\frac{2j\pi}{k} + \frac{1}{k} \arg z$ .

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

#### Construction of permutation-twisted modules

- Note that the left hand side is the branched covering of the right hand side by  $\mathbb{P}^1 \to \mathbb{P}^1, \gamma \mapsto \gamma^k$  with  $0, \infty$  the branched points.
- General case: Let Orb(g) be the set of g-orbits in E. For each g-orbit o we choose a V-module W<sub>o</sub>. Then W = ⊗<sub>o∈Orb(g)</sub> W<sub>o</sub> can be equipped with a g-twisted module such that Y<sub>W</sub> is the tensor product of all twisted vertex opertors on W<sub>o</sub> defined above.

8/24

Physics:

 Bantay ('98, '02) pointed out this twisted/untwisted correspondence. But he mainly considered *unbranced* coverings (of elliptic curves).

Conformal nets:

 Kawahigashi-Longo-Müger ('01) used (genus-0) Z<sub>2</sub> permutation CFT (i.e. (12)-twisted modules of A ⊗ A where A is a conformal net) to study the relation between 1. the "complete rationality" of A and 2. the modularity of Rep(A).

イロト イヨト イヨト ・

#### Conformal nets (continued):

- The methods of conformal nets (a family of operator algebras indexed by open intervals on S<sup>1</sup>) are seemingly only applicable to genus-0 CFT. But modularity, S-matrices, etc. are genus-1 phenomena. So KLW's work shows that genus-0 Z<sub>2</sub>-permutation twisted CFT contains useful data of genus-1 (or higher genus) untwisted CFT!
- A retrospective explanation: Conformal blocks for permutation-twisted V<sup>⊗E</sup>-modules on P<sup>1</sup> correspond to conformal blocks for untwisted V-modules of a branched covering C of P<sup>1</sup>, which is possibly of higher genus.

< ロ > < 同 > < 回 > < 回 > < 回 > <

Later works on conformal nets: Longo-Xu ('04), Kac-Longo-Xu ('05), Liu-Xu ('19), etc. Note that KLX computed many fusion rules (i.e. dimensions of the space of conformal blocks associated to 3-pointed ℙ<sup>1</sup>) for cyclic (i.e. Z<sub>n</sub>) permutation-twisted conformal net modules. Their result suggests a relation between genus-0 permutation orbifold CFT and higher genus untwisted CFT. But no (geometric) explanation was given there.

VOAs:

- Constructing twisted modules (no conformal blocks or fusion rules): Barron-Dong-Mason ('02), Dong-Xu-Yu ('21).
- Computing (certain) fusion rules among cyclic permutation-twisted modules: Dong-Li-Xu-Yu ('19)

Tensor categories and modular functors:

- Barmeier-Schweigert ('11): constructing **topological** branched coverings, i.e., explains the twisted/untwisted correspondence in the topological setting.
- Bischoff-C.Jones ('19) and Delaney ('19): developed algorithms of computing twisted-permutation fusion rules for any *G*, but explicit yet uniform results of computation are restricted to the **cyclic** case. Did *not* explain the correspondence.
- When applying these results to the explicit VOA or conformal net contexts, it is not clear how to identify the explicitly constructed twisted modules (e.g. via Barron-Dong-Mason) with the abstract objects in the categorical approaches.

12 / 24

## Conformal blocks

- Let X = (C; x<sub>1</sub>,..., x<sub>N</sub>; η<sub>1</sub>,..., η<sub>N</sub>) be a (possibly disconnected) N-pointed Riemann surface with local coordinates, where x<sub>1</sub>,..., x<sub>N</sub> ∈ C are distinct points, each component of C contains some x<sub>i</sub>, and each η<sub>i</sub> is a local coordinate at x<sub>i</sub>. (Namely, η<sub>i</sub> : U<sub>i</sub> → C is injective and holomorphic for some neighborhood U<sub>i</sub> ∋ x<sub>i</sub>, and η<sub>i</sub>(x<sub>i</sub>) = 0.)
- To each x<sub>i</sub> we associate a V-module W<sub>i</sub>. Then a conformal block is a linear functional φ : W<sub>•</sub> = W<sub>1</sub>⊗····⊗ W<sub>N</sub> → C satisfying certain covariance property.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ ののの

## Conformal blocks

- Covariance property (E.Frenkel-BenZvi '04): For all i, the expression f<sub>i</sub> = φ(w<sub>1</sub> ⊗ · · · ⊗ Y(v, η<sub>i</sub>)w<sub>i</sub> ⊗ · · · ⊗ w<sub>N</sub>) (as a (formal) meromorphic function on U<sub>i</sub> ∋ x<sub>i</sub> with (finite) poles at x<sub>i</sub>) can be analytically continued to the same meromorphic section on C with possible poles only at x<sub>1</sub>,..., x<sub>N</sub>.
- If  $\mathbb{W}_i$  is twisted, this definition no longer makes sense since  $f_i$  is not a single-valued function of  $\eta_i$ .

#### Basic facts about (untwisted) conformal blocks

(Beilinson-Feigin-Mazur, Tsuchiya-Ueno-Yamada, Zhu, Huang, Nagatomo-Tsuchiya, Damiolini-Gibney-Tarasca, G., etc.) Assume V is  $\mathbb{N}$ -graded and  $C_2$ -cofinite, each  $W_i$  is finitely-generated.

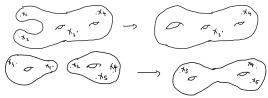

- Let CB(𝔅, 𝔍<sub>•</sub>) be the space of conformal blocks associated to 𝔅 and the assigned modules. Then dim CB(𝔅, 𝔍<sub>•</sub>) < +∞ and is independent of η<sub>•</sub>, the complex structure of C, and the locations of x<sub>•</sub> (if C is connected).
- If  $\mathbb{W}_1$  is dual to  $\mathbb{W}_2$ , then the contraction

$$\phi(\underbrace{\cdot \otimes \cdot} \otimes w_3 \otimes \cdots \otimes w_N)$$

is convergent and is a conformal block associated to  $\mathscr{SX}$  (the sewing of  $\mathfrak{X}$  along  $\eta_1^{-1}(S^1), \eta_2^{-1}(S^1)$ ) when the sewing makes sense geometrically.

## Basic facts about (untwisted) conformal blocks

• Self-sewing and disjoint sewing:

Factorization: Assume V is also rational. Fix W<sub>3</sub>,..., W<sub>N</sub>. Then any element of CB(𝒴𝔅, W<sub>3</sub> ⊗ ··· ⊗ W<sub>N</sub>) is a linear combination of sewing (contraction) of elements of CB(𝔅, W<sub>1</sub> ⊗ W<sub>1</sub><sup>∨</sup> ⊗ W<sub>3</sub> ⊗ ··· ⊗ W<sub>N</sub>) (for possibly several W<sub>1</sub> and its dual module W<sub>1</sub><sup>∨</sup>).

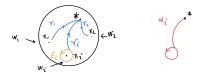

< □ > < □ > < □ > < □ >

## Basic facts about (untwisted) conformal blocks

- Special cases of this sewing/factorization include: the associativity isomorphisms of Rep(𝔍), modular invariance, etc.
- A variant of factorization:  $\dim CB(\mathscr{SX}, \mathbb{W}_3 \otimes \cdots \otimes \mathbb{W}_N) = \sum_{[\mathbb{W}_1]} \dim CB(\mathfrak{X}, \mathbb{W}_1 \otimes \mathbb{W}_1^{\vee} \otimes \mathbb{W}_3 \otimes \cdots \otimes \mathbb{W}_N)$  where the sum is over all equivalence classes of irreducible  $\mathbb{V}$ -modules  $[\mathbb{W}_1]$ .
- This factorization gives us an explicit algorithm of expressing the dimensions of spaces of conformal blocks in terms of those with lower genera or fewer marked points, and ultimately in terms of fusion rules (i.e. those of genus-0 and 3 marked points).

・ロト ・四ト ・ヨト ・

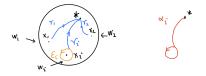

## Twisted conformal blocks

Consider for simplicity the genus-0 cases.

- Consider *N*-pathed sphere  $\mathfrak{P} = (\mathbb{P}^1; x_{\bullet}; \eta_{\bullet}; \gamma_{\bullet})$  where each  $\gamma_i$  $(1 \leq i \leq N)$  is a path in  $\mathbb{P}^1 \setminus x_{\bullet}$  from  $\gamma_i(0)$  (near but not equal to  $x_i$ ) to  $\gamma_i(1) = \bigstar$  (independent of *i*) such that  $\eta_i(\gamma_i(1)) > 0$ .
- Let ε<sub>i</sub> be a small anticlockwise circle around x<sub>i</sub> from and to γ<sub>i</sub>(0), and let α<sub>i</sub> = γ<sub>i</sub><sup>-1</sup> \* ε<sub>i</sub> \* γ<sub>i</sub>. Then the homotopy class [α<sub>i</sub>] is an element of Γ := π<sub>1</sub>(ℙ<sup>1</sup>\x<sub>•</sub>, ★). We assume that Γ is generated by all [α<sub>i</sub>].

## Twisted conformal blocks

Let W<sub>i</sub> be a g<sub>i</sub>-twisted U-module. Then a conformal block associated to W<sub>•</sub> and 𝔅 is a linear functional
 ψ : W<sub>•</sub> = W<sub>1</sub> ⊗ ··· ⊗ W<sub>N</sub> → C such that the expression
 ψ(w<sub>1</sub> ⊗ ··· Y(u, η<sub>i</sub>)w<sub>i</sub> ⊗ ··· ⊗ w<sub>N</sub>)

(where we take  $\arg \eta_i(\gamma_i(0))$  to be 0 recalling the assumption  $\eta_i(\gamma_i(0)) > 0$ ) for all *i* can be extended to a common holomorhic section on a neighborhood of  $\bigcup_i \operatorname{Rng} \gamma_i$ , and furthermore to a multivalued holomorphic section on  $\mathbb{P}^1 \setminus x_{\bullet}$ .

We return to the setting  $\mathbb{U} = \mathbb{V}^{\otimes E}$ ,  $G \leq \operatorname{Aut}(E)$ ,  $g_i \in G$ , and consider  $\mathcal{W}_i$  a  $g_i$ -twisted  $\mathbb{V}^{\otimes E}$ -module from the BDM-construction, which equals  $\bigotimes_{o \in \operatorname{Orb}(g_i)} \mathbb{W}_{i,o}$  as a vector space, and each  $\mathbb{W}_{i,o}$  is a  $\mathbb{V}$ -module. (We assume:  $\mathbb{V}$  and  $\mathbb{W}_{i,o}$  are  $\mathbb{N}$ -graded with finite-dimensional graded subspaces).

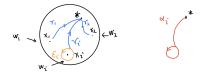

Theorem (G. '21)

A linear functional on  $\bigotimes_{i=1}^{N} \mathcal{W}_{i} = \bigotimes_{i=1}^{N} \bigotimes_{o \in \operatorname{Orb}(g_{i})} \mathbb{W}_{i,o}$  is a conformal block associated to  $\mathcal{W}_{1}, \ldots, \mathcal{W}_{N}$  and  $\mathfrak{P}$  iff  $\phi$  is a conformal block associated to all  $\mathbb{W}_{i,o}$  and a pointed compact Riemann surface  $\mathfrak{X}$ described below. (Note that all  $\mathbb{W}_{i,o}$  correspond bijectively to the marked points of  $\mathfrak{X}$ .)

In particular, the two spaces of conformal blocks in the theorem have the same dimension.

Recall in general that if Y is a connected manifold, ★ ∈ Y, then the finite connected covering spaces X → Y correspond bijectively to the (conjugacy classes of) cofinite subgroups of π<sub>1</sub>(Y, ★), i.e., a transitive action of π<sub>1</sub>(Y, ★). In general, finite covering spaces X → Y correspond bijectively to actions of π<sub>1</sub>(Y, ★) on some finite sets E. The components of X correspond bijectively to the π<sub>1</sub>(Y, ★)-orbits of E.

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

- 𝔅 = (C; marked points; local coordinates) where we have a holomorphic branched covering φ : C → ℙ<sup>1</sup> which is unbranched outside φ<sup>-1</sup>(x<sub>•</sub>). φ<sup>-1</sup>(x<sub>•</sub>) is the set of marked points of 𝔅.
- Let Γ = π<sub>1</sub>(P<sup>1</sup>\x<sub>•</sub>, ★) act on E such that [α<sub>i</sub>] acts as g<sub>i</sub>. (The existence of Γ adds constraints on g<sub>i</sub>. If such action does not exist, we understand that there are no non-zero conformal blocks.) Then the unbranched covering C\φ<sup>-1</sup>(x<sub>•</sub>) → P<sup>1</sup>\x<sub>•</sub> is the one corresponding to the action Γ → E.

- The way we associate each W<sub>i,o</sub> to a marked point of 𝔅 is more complicated. (See the intro of my article.)
- But note that the genus of each connected component of C can be computed via the Riemann-Hurwitz formula: Let Ω be any Γ = π<sub>1</sub>(ℙ<sup>1</sup>\x<sub>•</sub>, \*) orbit (equivalently, G-orbit) in E, which corresponds to a component C<sup>Ω</sup>. Then the genus is

$$g(C^{\Omega}) = 1 - |\Omega| + \frac{1}{2} \sum_{i=1}^{N} \sum_{o \in \operatorname{Orb}^{\Omega}(g_i)} (|o| - 1)$$

where  $\operatorname{Orb}^{\Omega}(g_i)$  is the set of  $g_i$ -orbits of  $\Omega$ .

#### Example

Let  $\mathfrak{P} = (\mathbb{P}^1; 0, a, b, \infty)$  where  $a \neq b \in \mathbb{C} \setminus \{0\}$ . Associate  $\sigma = (12)$ -twisted modules of  $\mathbb{V} \otimes \mathbb{V}$  to the four marked points. Then the associated branched covering is the elliptic curve  $\zeta^2 = z(z-a)(z-b)$  (with 4 marked points ) projected onto the *z*-coordinate.

 Thus, when V is C<sub>2</sub>-cofinite and rational, the fusion rules among permutation-twisted V<sup>⊗E</sup>-modules can be expressed by those among (untwisted) V-modules thanks to the factorization of (untwisted) conformal blocks.
